Self-Spreading Vaccines Are No Myth...It's Hard Science Johns Hopkins Confirmed Them - Covid Genocide Is Here

By Vince Morreno
5-1-21

Jeff,

Self spreading vaccines are no myth. Johns Hopkins University confirms it. See attached page down below. I have their original document.

You'll get the vaccine whether you like it or not.

Self propagating vaccines were conceived by Australian Nobel Virologist Sir Macfarlane Burnet. You know about him. As you know, my interest arose when I bought his former house in 2013 and strange things happened. I looked into his life. I was so shocked, I proposed getting a priest in to do an exorcism the house. No joke.

Burnet with his protégé Sir Gustav Nossal, and the CSIRO, developed the Myxomatosis virus. First used in Australia on rabbit plagues. It was the world's first self-propagating virus that recognized - self, and acted as a vaccine which caused immune suppression. AIDS for rabbits!

Australia is ground zero for the unfolding Covid genocide.

Burnet and William Gates were friends.

William Gates started the William Gates foundation, later renamed the Bill & Melinda Gates Foundation. Burnet's protégé, Gustav Nossal went on to work for the foundation and WHO after Burnet died in 1985. He carried forth the Burnet-Gates Senior plan for genocide.

Gates, Sr. and Burnet conceived and financed the genocidal message on the Georgia Guide stones. Think about that.

The two were friends with the eugenists William Shockley who engaged a friend Dr Herman Kermet to undertake the works incognito. I trust you watched the doco, Dark Clouds over Elberton.

The US bio weapons lab at Fort Detrick commissioned Burnet who proposed unleashing an Influenza Carona Virus on China in 1947. The technology of the time couldn't guarantee no virus blowback, so it was shelved. He was also working for the British equivalent. Burnet was seriously connected

In the late 1970s, the Australian government CSIRO developed CRISPR gene editing for Myrtleford, Victoria tobacco farmers. They originally called it Gene Shears. The science minister of the time, Barry Jones, stated the technology would change the world. It has. We've seen none of the full horrors yet of chimera humans and ethic DNA targets bioweapons which was Burnet's dream.

The CRISPR biotech is being used for the Covid Myxoma self-spreading 'vaccine' bioweapon.

Melbourne, Australia is ground zero for Covid technology and the Gates family plan. It was also ground zero for curfews, lockdowns, freedom of movement denial and mask wearing. The techniques spread around the globe.

Both Burnet and Gates were eugenists connected to the London Eugenics society (rebranded the Gaulton institute to drop the term 'eugenics'). Bill Gates has been marinated in this stuff from his childhood. He is executing the plans of his father and the maniacal Sir Macfarlane Burnet.

In 1967, Burnet wrote 'Endurance of Life' (1978). It received a critical reception for his eugenist and sociobiological views. It provoked great controversy. Those views included, capital punishment to rid society of undesirables and mentally unfit, abortion for population selection and euthanasia for the unworthy. This particularly included killing the disabled and elderly when they were no longer productive. This is despite he, himself, being 79 when he wrote that book. Burnet's other 13 books he wrote in retirement include almost word for word what we read on the Georgia Guidestones. He wrote the Guidestones tenets with lawyer pal William Gates, who was a close friend of David Rockefeller - see attached photo.

Do you get the picture, Jeff? We are watching a genocidal transgenerational plan unfolding. Bill Gates is executing it on behalf of dead men and others who shared their goals.

This is diabolical. Satanic. Civilization in facing a hugely clear and present danger.

- Vince

Self-Spreading Vaccines

WHAT IS THE TECHNOLOGY?

Self-spreading vaccines—also known as transmissible or self-propagating vaccines—are genetically engineered to move through populations in the same way as communicable diseases, but rather than causing disease, they confer protection. The vision is that a small number of individuals in the target population could be vaccinated, and the vaccine strain would then circulate in the population much like a pathogenic virus. These vaccines could dramatically increase vaccine coverage in human or animal populations without requiring each individual to be inoculated. This technology is currently aimed primarily at animal populations. Because most infectious diseases are **zoonotic**,⁴⁰ controlling disease in animal populations would also reduce the risk to humans.

There are 2 main types of self-spreading vaccines: recombinant vector vaccines and live viral vaccines. Recombinant vector vaccines combine the elements of a pathogenic virus that induce immunity (removing the portion that causes disease) with a transmissible viral vector. Cytomegalovirus is one candidate vector for recombinant vaccines, because

it is highly species-specific and moderately transmissible. Live viral vaccines are attenuated, meaning that the vaccine viruses are much less pathogenic than wild-type and would be similar to the oral polio vaccine or the live attenuated influenza vaccine (LAIV) in that those vaccines can sometimes transmit from person to person.

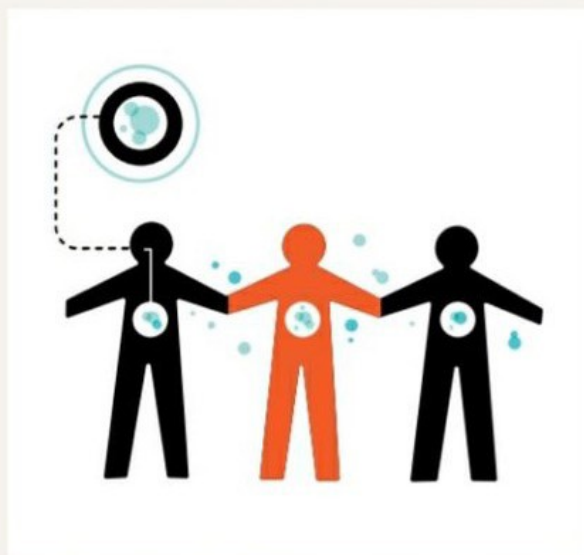

Although there are substantial technical challenges in genetically engineering viruses, synthetic biology tools such as CRISPR/Cas9 are likely to aid researchers in overcoming these hurdles in the coming years. Self-spreading vaccines have already been used to protect wild rabbits from myxomatosis and to control Sin Nombre virus in rodent populations. Additional work is targeting Ebola virus in apes and bats, Lassa virus in rats, and bovine tuberculosis in badgers.

WHAT PROBLEM DOES THIS SOLVE?

The most practical and useful application of self-spreading vaccines would be to control disease spread in wild animal populations (also known as sylvatic spread). A vaccine would be administered to a few selected animals in hotspots among target populations including nonhuman primates, bats, or rodents. The vaccine would then spread within the target

population, eliminating the need to vaccinate each animal. Successful disease control in animal populations could limit the number of infected animals and thereby reduce the opportunity for the disease to spill over into humans, thus stopping outbreaks in humans before they ever emerge. Such a sylvatic strategy would reduce the overall number of outbreak opportunities in humans, but it could not interrupt an outbreak once it becomes established in humans.

In the event of a grave public health threat, self-spreading vaccines could potentially be used to broadly inoculate human populations. Like the approach in animals, only a small number of vaccinated individuals would be required in order to confer protection to a larger susceptible population, thus eliminating the need for mass vaccination operations, including PODs.
